

User Roles and Access Model

Foundation document | Version 0.1 | 07 August 2026

Access model

Access is the intersection of tenant membership, active module/feature, role permission, reporting scope, and record ownership. Roles are templates; granular permissions are the enforcement unit. Tenant Owners may delegate access but cannot bypass platform controls.

Platform Super Admin

Operates STF across tenants: tenant lifecycle, plans, module catalog, support access policy, platform analytics, and controlled impersonation/support with audit. Cannot casually browse payroll or employee files; exceptional access must be justified, time-bound, and logged.

Tenant Owner

Full company control: company settings, admins, modules within plan, policies, payroll approval, reports, and retention choices. May appoint Super Admins inside the tenant.

Tenant Super Admin and Admin

Manage users, employees, policies, attendance exceptions, leave, tasks, reports, and approved modules. Payroll access should be separately permissioned. Super Admin is a delegated operational authority; Admin is configurable by permission set.

HR

Maintains employee records, documents, leave workflow, attendance review, and payroll inputs. HR cannot change subscription, platform configuration, or sensitive owner controls unless explicitly granted.

Manager and Team Leader

View and manage their reporting tree; assign/review tasks; approve requests when configured; see limited reports. They should not see confidential payroll, bank, or identity data by default.

Employee and Viewer

Employee views and acts on own attendance, leave, tasks, documents, payslips, and notices. Viewer is read-only and must have a defined record scope.

Minimum sensitive permissions

Separate permissions for salary view/edit/approve, bank details view/edit, document download, location view, attendance override, leave approval, policy edit, task reassignment, export, and audit-log view.

Give this to Claude

Create a role-and-permission management UX that starts with safe role templates and permits granular overrides. Make record scope and sensitive-data access visible before saving changes.
